# User study: 2 In-game report

## User data:

Number of users: 14

Male users: 11Female users: 3

Interaction per user: 3Total interaction tasks: 84

NUI: 42 tasksUNUI: 42 tasks

# Distraction time:

Average distraction time:

UNUI: 1.068 secondsNUI: 0.357 second

# Average individual distraction time :

# <u>UNUI:</u>

Window: 1 secondMirror: 1.16 seconds

• Radio:

On/off: 1.2 seconds

Adjust volume: 1 secondChange track: 0.75 second

#### <u>NUI:</u>

Window: 0.2 secondMirror: 0.58 second

Radio

On/off: No distraction
Adjust volume: 1 second
Change track: No distraction

Conclusion based on distraction time analysis:

- UNUI is three times more distractive in comparison to NUI
- In UNUI mirror interaction is more distractive (due to two stage interaction)

• In NUI adjusting volume is more distractive ( due to voice + interaction)

# Collisions:

• Total: 7

During NUI: 2 (28% of total collisions)
During UNUI: 4 (57% of total collisions)
No interaction: 1 (15% of total collisions)

## Probability of collision during interaction tasks:

UNUI: 0.1 (1 in 10 interactions)NUI: 0.04 (1 in 21 interactions)

## Other possibilities:

• During no interaction: 0.02 (1 in 42 interactions)

• Probability of no collisions during interaction: 0.84 (35 in 42 interactions)

#### Conclusion based on number of collisions:

- Interacting with UNUI has two times more probability of a collision than NUI
- Collision happens once in 10 interactions during interacting with UNUI
- Collision happens once in 21 interactions during interacting with NUI
- NUI interaction is much safer compared to UNUI interaction method.

# False positives:

During NUI: 3 timesDuring UNUI: 7 times

# Conclusion based on false positives:

- UNUI is twice prone to errors than NUI
- NUI is more reliable.

#### Results

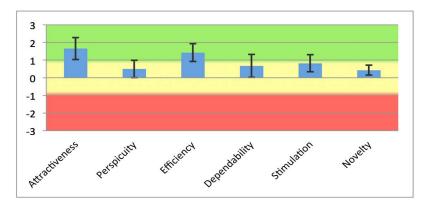

You can interpret the means of the scales. The UEQ does not produce an overall score for the user experience. Because of the construction of the quest the mean over all scales), since this value can not be interpreted properly. The values for the single items are listed to allow you to detect outliers in the  $\epsilon$  same scale this can be a hint that the item is misinterpreted (for example because of a special context in your evaluation) by a higher number of participal values between -0.8 and 0.8 represent a *neural evaluation* of the corresponding dimension, values > 0,8 represent a *positive evaluation* and values < -0, The range of the scales is between -3 (horribly bad) and +3 (extremely good). But in real applications in general only values in a restricted range will be  $\epsilon$  different opinions and answer tendencies, for example the avoidance of extreme answer categories, extremely unlikely to observe values above +2 or be Thus, even a quite good value of +1.5 for a scale looks from the purely visual standpoint on a scale range of -3 to +3 not as positive as it rescale means. Use the figure with the reduced scale -2 to +2 if you communicate the results to persons that have not much knolwedge explain in detail how building mean values and answer tendencies influence the observed data.

#### Correlations of the items per scale and Cronbachs Alpha-Coefficient

Items that belong to the same scale should show in general a high correaltion. The Alpha-Coefficient (Cronbach, 1951) is a measure for the consistence of a scale. There is no generally accepted rule how big the value of the coefficient should be. Many authors assuem that a scale should show an alpha value > 0.7 to be considered as sufficiently consistent. However, from an methodological standpoint such a use of a cut-off criterium is not really well-founded (see for example Schmitt, N., 1996). Especially if you have only a small sample the value of the Alpha-Coefficient should be interpreted carefully.

If the value of the Alpha-Coefficient for a scale shows a massive deviation from a reasonable target value, for example 0.7, this can be a hint that some items of the scale are in the given context interpreted by several participants in an unexpected way. In such cases the corresponding scale should be interpreted very carefully.

#### **Interview Questions:**

Personal interviews were conducted with the user to find his opinion on the system and also to know the difficulties that he faced personally while using the system. The following questions were asked in the Interview session.

- 1. Which method (Natural or Conventional) will you use if you have the choice of both in a car of your own?
- 2. How was your overall experience about the system?
- 3. What do you feel about the cognitive load of the proposed system?
- 4. Did you face any difficulties in the system?
- 5. Any suggestions for Improvement?

# Conclusions based on the feedback from users:

- When we look into the ratio, 30 % of users chose natural,30% chose both whereas 40 % of users conventional.
- The Idea looks innovative, since it makes driving enjoyable. But it needs lot of improvements to adopt it into cars.
- Cognitive load is not a serious concern in general but some interactions are causing distractions at some particular instances.
  (e.g) when a user wants to adjust the side mirror to see something behind he has to adjust by seeing at the mirror as the user cannot see whether he could see the road properly without seeing the mirror itself, which causes lot of distraction.

# Suggestions for Improvement:

- Position of sensors should be modified.
- Increase the session for each Interaction. It would be annoying to restart the each interaction from start.
- Feedback icon should be closer to the eyesight to make driving more comfortable
- Since everyone is new, needs more training on the system to get acquainted to proposed methodology
- Leap should have more coverage area to operate the gestures freely.
