# Virtual Reality

## VR Displays & Stereo Rendering

G. Zachmann  
University of Bremen, Germany  
[cgvr.cs.uni-bremen.de](http://cgvr.cs.uni-bremen.de)

# The Kinds of VR Displays

- Autostereo Monitor
- *Head-Mounted Displays (HMDs)*
- *Head-Coupled Displays (HCDs)*
- *Immersive projection displays (IPDs)*
  - *"Powerwall"*
  - *Workbench*
  - *Cave*
- "Exotic" displays:
  - Retinal displays
  - Holographic displays
  - ...

# Stereo Monitor (mostly Autostereo)

- Sometimes called "*Fishtank VR*"
- Advantages:
  - Inexpensive
  - Resolution up to 1900 x 1600
  - Well accepted by users
  - No special requirements on the environment/setting
  - Some 3D capabilities
- Disadvantages:
  - Small Field-of-View (FoV)
  - No immersion
  - Very limited working volume
  - "*Stereo frame violation*" is very common

- Interesting things you can do with a simple monitor: the "Reaching-Idea"

- The problem with a small FoV:  
there is **no immersion!**

# Head-Mounted Displays (HMD)

- First "true" VR display
- Technologies / characteristics:
  - HMDs using LCDs (sometimes CRTs)
  - Weight:
    - Small FoV → lightweight; large FoV → heavy
- Advantages:
  - Kind of "surround display"
  - Very good immersion
  - No "*stereo frame violation*"
  - Large working volume
  - *Low-end models* are inexpensive
  - Almost no special requirements on the working environment

- Disadvantages:
  - Uncomfortable when used for a prolonged time ("*invasive interface*")
  - Distortions
  - Real environment is shut off (good for immersion, bad for collaboration and self-embodiment)
  - Manipulation of real controls is difficult (e.g., in mockup of cockpit)
  - Every participant needs an HMD (bad: expensive, good: everybody has correct perspective in VE)
- Actually, HMDs hve been invented a long time before "VR"

*Bell Helicopter, 1967*

# Head Coupled Displays (HCD)

- HCD = HMD mounted on a "boom"
  - Advantage of HCDs over HMDs:
    - Possible to quickly "take the display off" for a moment; or users can just take a "quick peek" into the VE
    - Low weight on the head
    - Extremely good tracking comes built-in
  - Disadvantages compared to HMDs:
    - Smaller working volume
    - One hand is always occupied
    - Inertia
- Failed to gain market share

- Idea is (somewhat) similar to cinema theaters
- Setup: 1–6 walls on which VE is projected
- *Powerwall* = 1 wall (e.g., 3x6 meters)
- *Workbench* = 1 horizontal display surface (table)
- *Holobench, L-Shape* = 2 display surfaces, 1 vertical, 1 horizontal
- *Cave* = 3–6 walls

*Powerwall with back projection*

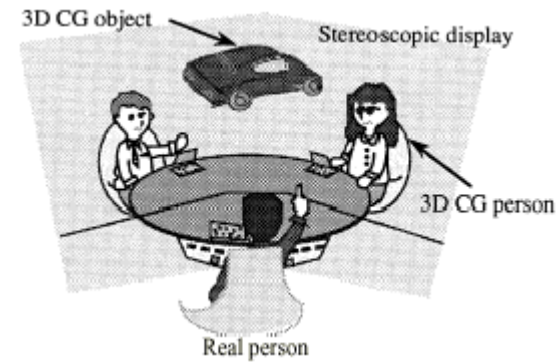

*Powerwall with front projection,  
(problems with that: edge blending, hot spots)*

- "*HeyeWall*", Darmstadt:
  - 24 tiles, 48 PCs
  - Total resolution: 18 Mio pixels (6144 x 3072) in stereo

# Example Application: Virtual Conference Room

Result: *1 shared workspace,*  
by way of coherently adjoining  
"desktop IPD"

# Workbench, L-Shape, etc.

*Workbench*

*Principle of the workbench*

*Tilting "workbench"*

*Holobench*

*3-wall cave*

*Schematic of the arrangement of the mirrors*

*5-wall cave, FhG-IGD, Darmstadt*

*6-wall cave, Alborg, DK*

## RealityDeck - Immersive Giga-Pixel Display

- Developed at Stony Brook U, New York
- 308x 30" LCD displays
- 2560 x 1600 resolution per display
- 1.2+ billion pixels of resolution in total
- 40'x30'x11' physical dimensions
- 85 dual quad-core, dual-GPU cluster nodes

<http://www.cs.stonybrook.edu/~realitydeck/>

# Curved Screens

# Curved Screen made out of 3D-TVs

- Idea: construct the walls of a Cave out of a (small) number of 3D TVs
- Advantage: reconfigurable relatively easily (just put the walls on wheels)

- Example: Wii + Dome + MacBook Pro

Source: Paul Bourke, University of Western Australia, <http://local.wasp.uwa.edu.au/~pbourke/>

- A modern "Sensorama":

*Immersa-Dome* from Aardvark Applications

Studie

[www.virtusphere.com](http://www.virtusphere.com)

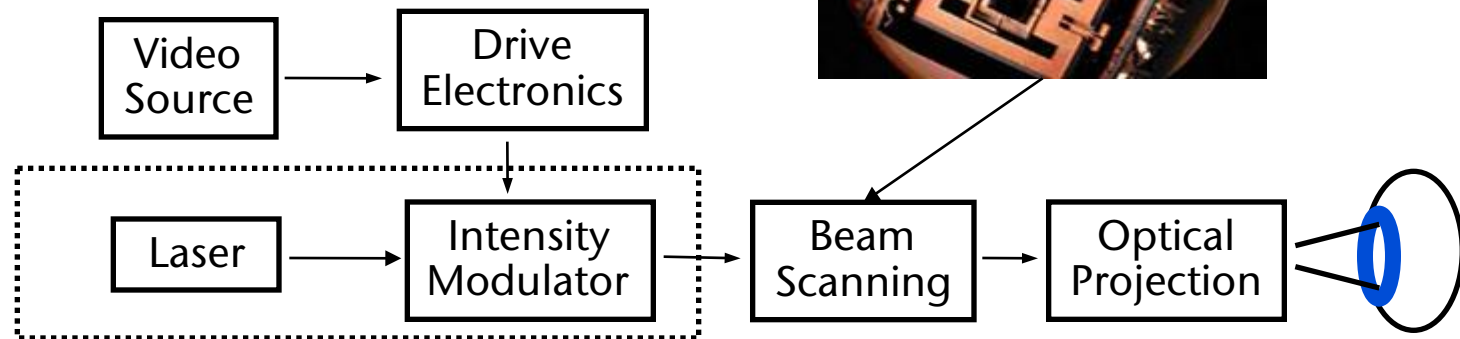

# Advantages and Disadvantages of IPDs

- Advantages:
  - Large resolution (currently up to ca. 1600 x 1280 per tile)
  - Large *field-of-view*
  - "*Non-invasive*"
  - No isolation of the real world
  - (Can accommodate Several Users)
  - *Cave*: turning the head results in small changes of the images  
→ problem of latency is reduced / not so prominent
- Disadvantages:
  - Size
  - Price (lots of projectors, lots of graphics cards)
  - Precision, calibration
  - Potentially "*stereoscopic violation*"
  - Correct view only for one *viewer* (unless a massive amount of hardware is used)

# Retina Displays (retinal displays)

- Idea:
  - Use the human retina as the display surface (all images from the outer world end up there anyway)
  - Use a laser to write the image by scanlines into the eye
- Advantages:
  - Can be miniaturized (potentially)
  - High contrasts, high brightness
  - Good for *see-through* displays
  - Small power consumption

*Retinal display*

*Design study*

# Holographic / Volumetric Displays

- Real 3-dimensional displays
- Advantages:
  - Provide correct perspective/view from *every* angle!
  - Coherence between accommodation and convergence
  - Depth of field (Tiefen(un-)schärfe)
- Holographic displays: algorithmic computation of holograms
- Problems:
  - Staggering amount of computational work
  - Colors
- Volumetric displays: voxel are projected into a volume (as opposed to a surface)
- Problems:
  - Size of data (e.g. 100 mega-voxels = 1000x1000x100 display resolution)
  - Occlusions?

- Example volumetric display:
  - $198 \times 768 \times 768 \approx 100$  million voxels
  - Frame rate: 20 Hz

- Fog ("fog screen"):
  - Laminar, non-turbulent air flow
  - Water droplets are "sandwiched" within the air flow

FogScreen

# The History of Stereo Images

- Euklid (4th century BC)
- Sir Charles Wheatstone (1838 )
- 1860: 1 million Stereoscopes sold
- 1950-ies:

- Today (demo):

# How to Project Stereo with only *one* Display Surface?

- Need some kind of *Multiplexing*

## 1. Temporal Multiplexing ("active stereo"):

- Typically 1 projector (e.g. monitor)
- Project/render alternatingly left/right image
- Synchronously, switch left/right glass of *shutter glasses* to pass-through
- Shutter glasses run with 120 Hz → 60 Hz framerate

## 2. Multiplexing by polarization ("passive stereo"):

- Usually 2 projectors displaying on same surface
- Project left/right simultaneously but with different Polarization of the light
- Polarization glasses let only left/right images pass, resp.

■ Kinds of polarization:

1. Linear polarization:

- Any direction perpendicular to direction of travel of light

2. Circular polarization:

- Left-handed / right-handed polarization

<http://www.colorado.edu/physics/2000/applets/polarization.html>

# "Color Multiplexing"

- Simple version: *Anaglyph stereo* (red-green stereo)

- Generalization ("*Infitec*", Dolby3D, spectral comb filter, wavelength multiplex):
  - Each of the primary colors must pass through a narrow band pass filter
  - Left & right eye get filters with interleaving band passes

- Problem:
  - Color fidelity

# The Problem of Multiple User and a Single IPD

- Problem with a single-tracked projection (stereo or mono): only the viewpoint of the tracked users is correct, only she will see a correct image!
- Example:

Image's perspective is correct for the user

Image's perspective is correct for the (real) camera

# Correct (Stereo-)Projection for Multiple Users

- Probably only possible for a small number of users
- *Temporally multiplexed:*
  - Framerate for multi-user stereo = Framerate for mono \* 2 · #User
- Infitec for several users:
  - Each user gets glasses with slightly shifted comb filters
  - With  $n$  users we need  $2n$  different comb filters → extremely narrow bands
- *Spatially multiplexed*
- Combination of the above

# Spatial Multiplexing

- Proj. surface is partitioned among users
- Consequence: interdependence between
  - Size of the *view frustum*
  - Working volume of users
  - D & radius of hole
- Example:

IllusionHole @ Siggraph 2001

- Combination of active and passive stereo, plus ingenious utilization of time-sequential projectors
- Recap from CG1:

time-sequential RGB with DLPs

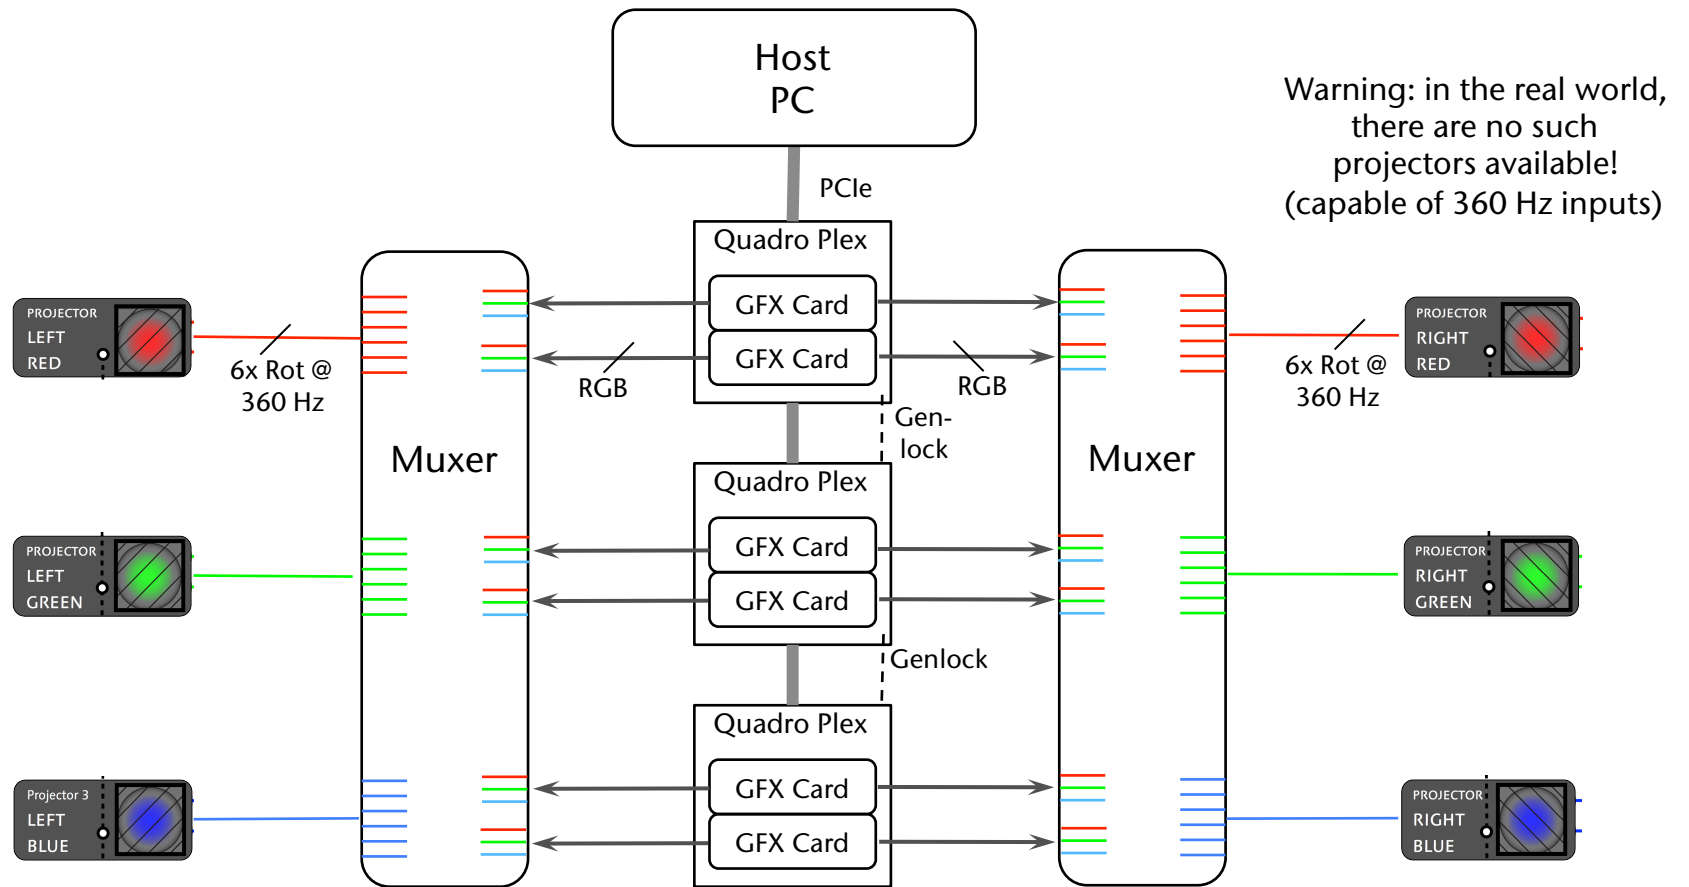

1. Modification: remove color wheel
2. Modification: each user gets shutter glasses that additionally has left/right polarization filters

- Must be fast enough to prevent cross-talk!

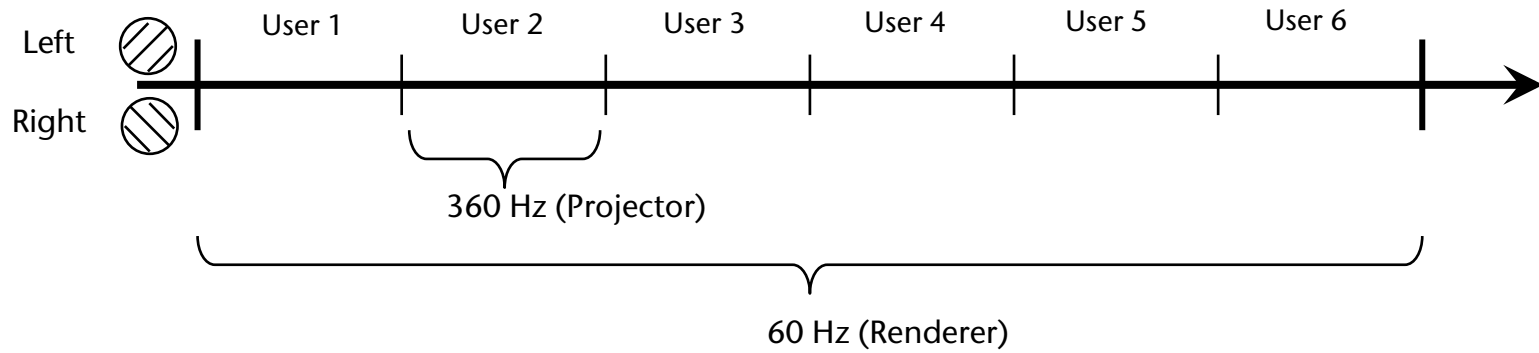

# The Hardware in *Principle*

- 6 stereo video streams are generated by 6 graphics cards in 1 PC
- Distribution of the video streams to the projectors via multiplexers

■ Timing:

■ Video:

# Outlook

- With *perspectively correct* projections for *each* user, the shared 3D space will become **coherent** for all users
- Consequence: direct communication (including pointing) in **co-located CSCW** is possible

Agrawala et al. 1997

Arthur et al. 1998

Kitamura et al. 2001

Agócs et al. 2006

# Interaction Issue with Multi-User-Stereo

- Navigation: the "navigator" controls the path for all users (and he sees only his own viewpoint!)
- Problem: the other users' viewpoint goes through walls
- Solution:
  - Adjust the paths of the other users automatically to bring them closer to the navigator's viewpoint
  - Fade away obstacles in the path of each user

# Stereoscopic Effect Based on the Pulfrich-Effect

- See slide "Pulfrich Effekt" in *Optische Täuschungen*

## ■ Der Pulfrich-Effekt

- 1922 entdeckt von Carl Pulfrich, deutscher Physiker
- Basis: dunkle Lichtreize lösen etwas später ein Signal aus als helle
- Beispiel: Video mit einer Sonnenbrille über einem Auge betrachten

### A Demonstration of The Pulfrich Effect

photography by Todd E. Gaul  
[www.photophile.com](http://www.photophile.com)

[http://www.youtube.com/watch?v=1mnWl\\_u\\_zBg](http://www.youtube.com/watch?v=1mnWl_u_zBg)

# Binocular / Stereo Vision

- Important "*depth cue*" (not the most important one)
- Works just up to a few meters (< 6 m, ca.)
- Disparity between the eyes =  $\delta_2 - \delta_1 = \gamma - \alpha$
- **Horopter** = locus of points in space with same apparent depth as the fixated object = point with 0-disparity
- **Parallax** on the screen:

# Measuring the Horopter

- First of all: not measuring it, but *constructing* it → Vieth-Müller Circle = theoretical locus of points in space that stimulate corresponding retinal points
- Measuring the Horopter with the "Apparent Fronto-Parallel Plane" method:
  - Subject is asked to arrange a series of objects so that there appears to be no depth difference between them

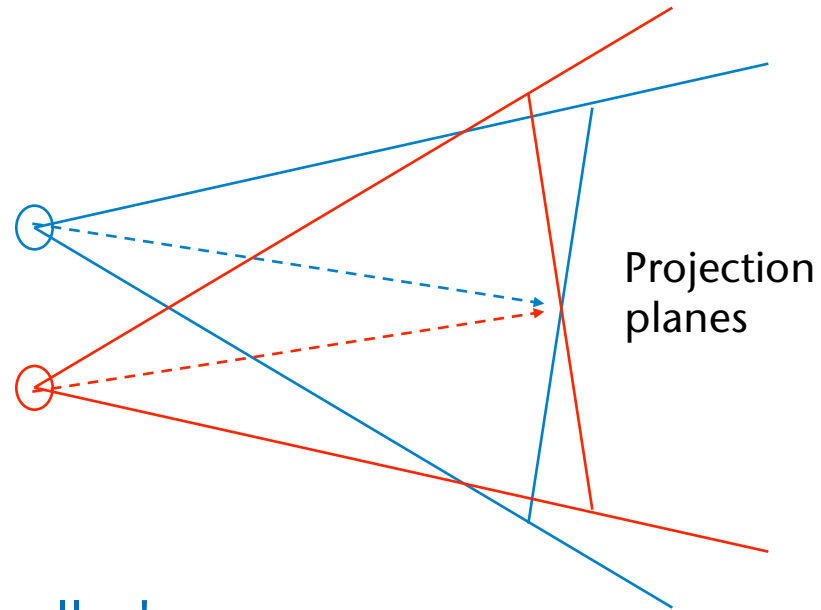

# Panum's Fusional Area

- There is a zone/range of depth around the horopter, where the brain is able to fuse the double image of an object  
→ Panum's Area of Fusion

- Wrong: konverging view vectors

- Problem: **verticale Parallax!**

Heads-up text  
Heads-up text

# Correct Stereoscopic Projection

- Right: parallel viewing vectors  
→ *off-axis perspective projection*

- Given  $i$ , aspect ratio  $w/h$ , horizontal FoV  $\alpha$ , near plane  $n$ , zero-parallax depth  $z_0$
- Determine *left/right/top/bottom* for `glFrustum()`
- Assumption: no head tracking, i.e., cyklop's eye is in front of the center of the zero parallax plane
- top* and *bottom* are as usual:

$$t = \frac{h}{W} l$$

- Example: *left* for left eye:

$$l_c = n \tan \frac{\alpha}{2}$$

$$l' - l_c = i \frac{z_0 - n}{z_0}$$

$$l = l_c + (l' - l_c) - i = l_c - i \frac{n}{z_0}$$

# Problems with Stereo Rendering: Depth aliasing

- This effect would occur, even if the Z-buffer was continuous!

# Digression: Accommodation and Convergence

- Two important terms that get confused very easily
- **Convergence** = counterrotating eye movement (around the vertical axis), so that the optical axes of the eyes intersect at some point (**fixation point**)
  - So that the fixated object appear on the center of the retina (has highest resolution)
- **Accommodation** = adjustment of the eyes' lenses to adapt for different distances
  - So that the fixated object appears sharp on the retina
    - (Personally, I am often times confusing **accommodation** with **focussing** ;-))

- The following image appears to be 3-dimensional, if you can decouple accommodation and convergence:

- "Magic Eye" images are constructed patterns such that corresponding points convey depth :

"depth image" for it

# A Problem with Distance Estimations in Stereo Images

- Effect: in a Cave or Powerwall, objects appear more distant than they are
- My Hypothesis:

- Solution: holographic or volumetric displays
  - Which have other problems ...

# Stereo is a "one man show"

- Why are stereoscopic images correct only for 1 viewpoint?

- Solution:
  - For 2 viewers: render 4 images; or
  - Holographic/volumetric displays

- 2 effects that can occur together:

- *Clipping*

- Depth from stereoscopic image

- Object is clipped, although *in front of* the projection surface
    - Consequence: conflicting *depth cues*  
→ *stereo violation*

- Example: lower left corner of the anaglyph mars image

# Rendering onto Several Projection Walls (e.g. Caves)

- Represent the real projection surfaces by a polygonal object (e.g., cube) in the VE
- Rotate each polygon (and viewpoint) to make it perpendicular to z-axis (standard OpenGL viewing transf.)
- Determine *left/right/top/bottom*, just like previously (for single proj. wall)
- Careful with the complete viewing/projection transformation! If set up exactly like single wall projections, then ...
  - Specular lighting will have discontinuities
  - Generated texture coords (by OpenGL) will be discontinuous

- Problem with specular lighting:  
an "infinite (OpenGL) viewer"

- Reminder:

$$specular : (s \cdot n)^{shiny}, s = \overline{VL} + (0, 0, 1)$$

- Consequence:  $s$  "jumps" if object crosses projection walls!

- Solutions:

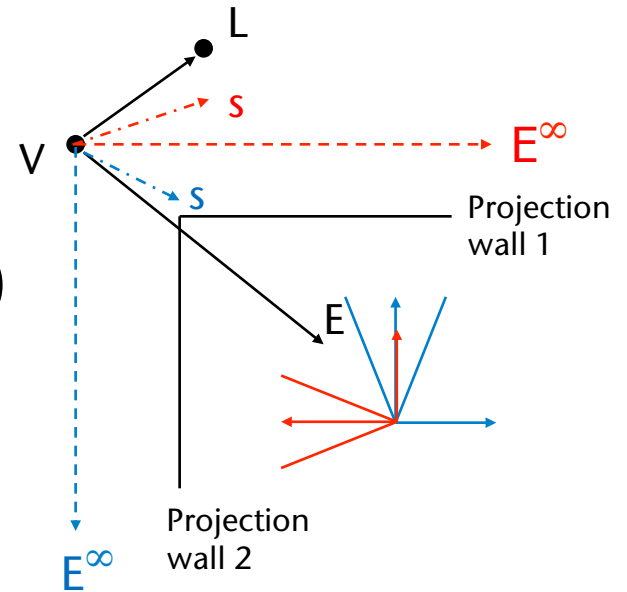

1. Use "local viewer" in OpenGL; then

$$s = \overline{VL} + \overline{VE}$$

remains consistent across walls (i.e., across projection matrices)

2. Or, multiply rotation matrix for each wall to the PROJECTION stack, instead of the MODELVIEW (which is the conventional way):

$$\mathbf{v}_{screen} = \underbrace{M_{projection} R_{wall}}_{GL\_PROJECTION} \underbrace{M_{viewpoint} M_{world}}_{GL\_MODELVIEW} \mathbf{v}_{object}$$

# The Model of a User's Head

$M_e$  = viewpoint transformation

$M_s$  = current sensor reading, relative to its zero calibration

$M_{rs}$  = transform. from head's rotational center to sensor

$M_{er}$  = transform. from "cyclop's eye" to head's rotational center

$T^l | T^r$  = translation to left/right eye

$$M_e = T_{l|r} M_{er} M_{rs} M_s$$

- Initialization:

```
glutInitDisplayMode (GLUT_DOUBLE | GLUT_RGB | GLUT_DEPTH |  
GLUT_STEREO) ;
```

- Rendering:

```
glDrawBuffer (GL_BACK_LEFT) ;  
glClear (...)  
glFrustum (...)  
traverse scene graph ..  
glDrawBuffer (GL_BACK_RIGHT) ;  
glClear (...)  
glFrustum (...)  
traverse scene graph ..
```

- Or: render with 2 different threads into 2 different graphics cards
- Or: side-by-side stereo (2 openGL viewports in one big window)

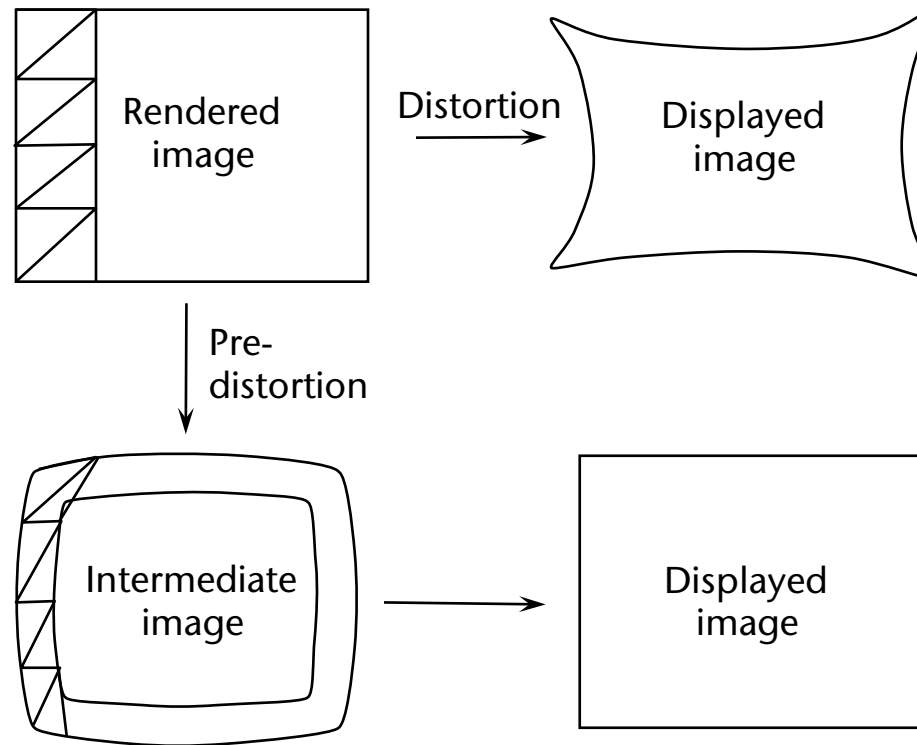

# Guidelines for Stereo Rendering

1. Make parallax not too big! (common error of novices)  
 $\pm 1.6^\circ \sim \text{parallax} \leq 0.03 \cdot (\text{distance to projection wall})$
2. Single object  $\rightarrow$  put zero-parallax plane at its center
3. Complete VE  $\rightarrow$  1/3 negative parallax, 2/3 positive parallax
4. Keep objects with negative parallax away from the border of the projection surface

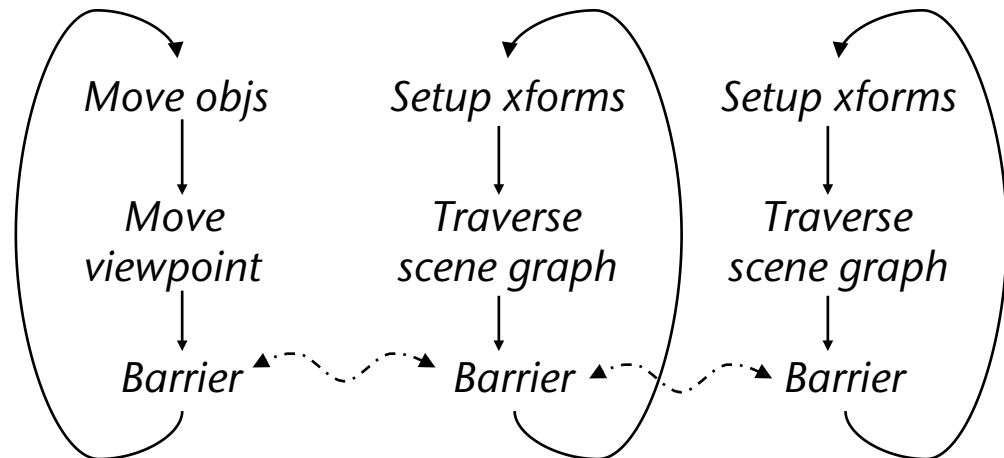

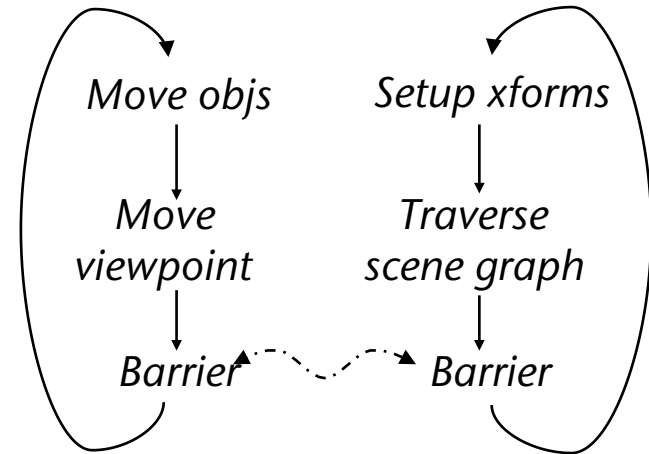

# Rendering on HMDs needs to be un-distorted

- Optics in HMDs usually cause some amount of distortion
- Idea: pre-distortion (using a texture)

# System Overview: the Rendering Loop

- 1 processor → everything serial
- 2 processors → app and renderer in parallel
- Stereo → 2 render processes (3 proc)
- In general:  $n$  walls in stereo →
  - $\geq n+1$  processors,  
 $n$  render processes
  - Better  $2n+1$  processors

# Crosstalk (Ghosting)

- **Crosstalk** = if one eye (also) sees the image meant for the other eye
  - Amount of crosstalk depends on technology

- Simulator sickness = more or less of the following symptoms (can sometimes occur with prolonged stay in flight simulators / virtual environments):
  - Nausea (including vomiting), eye strain, dizziness, drowsiness, blurred vision, headache, fatigue
- Cause is not entirely clear
- Common hypothesis: inconsistent sensory input to brain (e.g., mismatch between vision and vestibular organ (organ of equilibrium))
  - E.g., when staying below deck for a prolonged time
  - With latency between motion of platform and rendering in flight simulators
- Frequency: 20-40% with jet pilots
  - Occurs more frequently with experienced pilots than novices [sic]
- Other observations with mismatching sensory inputs:
  - In a rotating field when walking forward, people tilt their heads and feel like they are rotating in the opposite direction
  - If a person is walking on a treadmill holding onto a stationary bar and you change the rate the visuals are passing by, it will feel to the person like the bar is pushing or pulling on their hands
